

To access a Jupyter Notebook from another computer, you must configure the server to listen on all network interfaces instead of just localhost. [1]

Here are the two best ways to do this. **Method 1** is highly recommended because it is completely secure.

Method 1: Use Secure SSH Tunneling (Recommended)

This is the most secure method because you do not expose your machine to the public internet. [1, 2, 3]

1. **Start Jupyter on the Remote Machine:** Run this command on the computer hosting the notebook to prevent a local browser from launching.

bash

```
jupyter notebook --no-browser --port=8888
```

Use code with caution.

[1]

2. **Set up the Tunnel on the Client Machine:** Open the terminal or command prompt on your *other* computer and run the following command. Replace user and remote_ip with your hosting machine's details.

bash

```
ssh -N -f -L localhost:8080:localhost:8888 user@remote_ip
```

Use code with caution.

[1, 2, 3, 4, 5]

3. **Access the Notebook:** Open your local browser and navigate to **http://localhost:8080**. Enter the authentication token shown in your remote machine's terminal if prompted. [1]

Method 2: Open Jupyter to the Network (Local Network Only)

Use this option if both computers are connected to the same local Wi-Fi or Ethernet network. [1, 2]

1. **Set a Password:** Before opening up network access, secure your server by running this command on the host computer and setting a password:

bash

```
jupyter notebook password
```

Use code with caution.

[1]

2. **Launch with Global IP Binding:** Run the notebook by binding it to 0.0.0.0. This allows any machine on your local network to discover the server.

bash

```
jupyter notebook --ip=0.0.0.0 --no-browser
```

Use code with caution.

[1, 2, 3]

3. **Find the Host Computer's Local IP:** Find your internal network IP address (e.g., 192.168.1.50).
 - **Windows:** Run **ipconfig** in Command Prompt.
 - **Mac/Linux:** Run **hostname -I** or **ifconfig** in the Terminal. [1]
4. **Connect from the Client Machine:** Open the browser on your second computer and enter the host's local IP alongside the port number:

text

```
http://<host_local_ip>:8888
```

Use code with caution.

[1]

To streamline this process for regular use, you can permanently update these permissions inside the configuration file generated by the `jupyter notebook --generate-config` command. [1, 2]

If you run into connection errors, let me know:

- What **Operating System** is running on both computers?
- Are both devices on the **same Wi-Fi network**, or are you connecting across the **internet**?

I can help you troubleshoot firewall settings or configure automatic startup scripts.
